

## IDENTIFICATION OF MODELS AND DATA ANALYSIS B

<b>Enrollment year</b>	2014/2015
<b>Academic year</b>	2016/2017
<b>Regulations</b>	DM270
<b>Academic discipline</b>	ING-INF/04 (AUTOMATICS)
<b>Department</b>	DEPARTMENT OF ELECTRICAL, COMPUTER AND BIOMEDICAL ENGINEERING
<b>Course</b>	ELECTRONIC AND COMPUTER ENGINEERING
<b>Curriculum</b>	INFORMATICA
<b>Year of study</b>	3°
<b>Period</b>	2nd semester (01/03/2017 - 09/06/2017)
<b>ECTS</b>	6
<b>Lesson hours</b>	50 lesson hours
<b>Language</b>	Italian
<b>Activity type</b>	WRITTEN AND ORAL TEST
<b>Teacher</b>	DE NICOLAO GIUSEPPE (titolare) - 5 ECTS MARSEGLIA GIUSEPPE ROBERTO - 1 ECTS
<b>Prerequisites</b>	Basic notions of set theory, logic, calculus, function maximization.
<b>Learning outcomes</b>	Knowledge of basic notions of: estimation theory (maximum likelihood estimation, a-posteriori estimation); neural-based model identification; stochastic processes (mean, autocovariance, spectral density, optimal prediction); identification of ARMAX models. Ability to solve identification and prediction problems ranging from model formulation to the use of computer tools (Matlab) for parameter estimation and model simulation.
<b>Course contents</b>	System Identification deals with methodologies that enable the construction of mathematical models of systems and signals based on experimental data. In presence of complex systems whose behavior can be hardly reduced to known "laws of nature", the use of identification

techniques is often the only way to obtain models to be used in the context of forecasting, simulation, and control. The methods presented in the course are widely used in heterogeneous fields such as automation, biomedical engineering, econometry, hydrology, geophysics and telecommunications. The main properties (stability, input-output description in the time and frequency domains) of linear discrete-time systems are introduced. In the context of parametric estimation, the issues of model validation and model complexity are extensively discussed. Neural based identification is also illustrated and discussed, pointing out pros and cons with respect to standard approaches. The study of dynamic systems addresses three main topics: the optimal prediction of stationary stochastic processes (Wiener filtering), the identification of linear discrete-time systems, and spectral estimation (both nonparametric and maximum-entropy).

Estimation theory:

maximum likelihood estimation: properties and examples;  
 a-posteriori estimation, Bayes estimator;  
 cross-validation, model complexity and the bias-variance dilemma;  
 identification of nonlinear-in-parameter models.

Neural identification:

Radial basis function neural networks;  
 Multi-layer perceptron networks;  
 generalization, overfitting, selection of network size.

Stochastic processes and optimal prediction:

mean, autocorrelation, autocovariance, independence, incorrelation;  
 white noise, random walk, MA, AR, and ARMA processes, Yule-Walker equations;  
 stationarity, power spectral density, nonparametric spectral estimation;  
 spectral factorization, optimal prediction.

Identification of dynamic systems:

classes of dynamic models: output error, ARX, ARMAX;  
 prediction-error methods for system identification;  
 least-squares identification of ARX models: probabilistic analysis and persistent excitation.

**Teaching methods**

Lectures, practical class, workshops

**Reccomended or required readings**

Lecture notes (<http://sisdin.unipv.it/labsisdin/teaching/teaching.php>).

A. Papoulis. Probability, Random Variables, and Stochastic Processes. McGraw-Hill.

L. Ljung. System Identification: Theory for the User. Prentice-Hall.

**Assessment methods**

Written examination

**Further information**

Written examination
